Whether they are Bitcoin, Ethereum, XRP or Cardano, some projects are taking their place in the market at a very fast pace. The Hashgraph project, however, is making waves for very different reasons. Hashgraph is a distributed ledger technology that is designed to provide extremely fast and robust distributed consensus for processing data in a secure, decentralized and immutable way. It is essentially a keyless ledger built on top of directed acyclic graphs (DAG). What that means is that nodes, while searching the ledger for data to store or verify, and stores, while searching the ledger for data to confirm, never have a 'key' to the distributed ledger and thus, there is no central governance or control. It also means that transactions can be processed in a matter of microseconds, providing a very high transaction speed, and security, which lies in the fact that the distributed ledger is based on secure multi-party computation (SMC) mechanisms. It also means that the data on the ledger can never be corrupted by malicious nodes or kept by them. The data is distributed and thus, even if a malicious node takes control of part of the ledger, it cannot be able to alter transactions, which are stored in a cryptographically-secure fashion. In a nutshell, Hashgraph is a new, secure, decentralized and robust distributed ledger technology that was created by Hashing Ltd, a company that was set up in January 2014. What makes Hashgraph so unique is the fact that it is designed for very broad and niche use cases. It can be

utilized in situations where it is needed to achieve consensus and security or ensure the integrity and authentication of data that needs to be distributed as a distributed ledger. Companies and organizations can use Hashgraph for creation of custom ledgers, for storing and validating data in a secure fashion, for processing real-time, distributed data and for securing the data that they need to share with the outside world. Some of these use cases
